

## Lecture 21: Uncertainty 6

Victor R. Lesser  
CMPSCI 683  
Fall 2010

## Today's Lecture

### ◆ Decision Trees and Networks

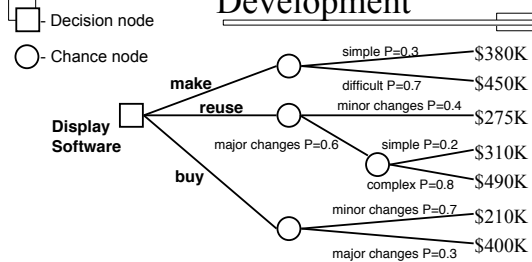

V. Lesser, CS683, F10

## Decision Trees

- ◆ A decision tree is an explicit representation of all the possible scenarios from a given state.
- ◆ Each path corresponds to decisions made by the agent, actions taken, possible observations, state changes, and a final outcome node.
- ◆ Similar to a game played against “nature”

V. Lesser, CS683, F10

## Example 1: Software Development

- ◆  $EU(\text{make}) = 0.3 * \$380K + 0.7 * \$450K = \$429K$
- ◆  $EU(\text{reuse}) = 0.4 * \$275K + 0.6 * [0.2 * \$310K + 0.8 * \$490K] = \$382.4K$
- ◆  $EU(\text{buy}) = 0.7 * \$210K + 0.3 * \$400K = \$267K$ ; best choice

V. Lesser, CS683, F10

## Example 2: Buying a car

- There are two candidate cars  $C_1$  and  $C_2$ , each can be of good quality (+) or bad quality (-).
- There are two possible tests,  $T_1$  on  $C_1$  (costs \$50) and  $T_2$  on  $C_2$  (costs \$20).
- $C_1$  costs \$1500 (\$500 below market value) but if it is of bad quality repair cost is \$700.
  - 500 gain or 200 lost
- $C_2$  costs \$1150 (\$250 below market value) but if it is of bad quality repair cost is \$150.
  - 250 gain or 100 gain
- Buyer must buy one of the cars and can perform at most one test. -- What other information?

V. Lamer, CS683, F10

## Example 2: Buying a car cont.

- The chances that the cars are of good quality are 0.70 for  $C_1$  and 0.80 for  $C_2$ .
- Test  $T_1$  on  $C_1$  will confirm good quality with probability 0.80 if  $C_1$ =good and will confirm bad quality with probability 0.65 if  $C_1$ = bad.
  - Imperfect information
- Test  $T_2$  on  $C_2$  will confirm good quality with probability 0.75 and will confirm bad quality with probability 0.70.

V. Lamer, CS683, F10

## Example 2: Buying a car cont.

What are the decisions and how can you judge their outcomes?

V. Lamer, CS683, F10

## Evaluating decision trees

1. Traverse the tree in a depth-first manner:
  - (a) Assign a value to each *leaf node* based on the outcome, then back-up outcome values
  - (b) Calculate the average utility at each *chance node* based on the likelihood of each outcome
  - (c) Calculate the maximum utility at each *decision node*, while marking the maximum branch
2. Trace back the marked branches, from the root node down to find the desired optimal (conditional) plan.

Finding the value of (perfect or imperfect) information in a decision tree.

V. Lamer, CS683, F10

## Additional Information

Buyer knows car  $c_1$  is good quality  
 $70\% P(c_1=\text{good}) = .7$

Buyer knows car  $c_2$  is good quality  
 $80\% P(c_2=\text{good}) = .8$

Test  $t_1$  check quality of car  $c_1$   
 $P(t_1=\text{pass}|c_1=\text{good}) = .8$   
 $P(t_1=\text{pass}|c_1=\text{bad}) = .35$

Test of  $t_2$  check quality of car  $c_2$   
 $P(t_2=\text{pass}|c_2=\text{good}) = .75$   
 $P(t_2=\text{pass}|c_2=\text{bad}) = .3$

V. Lammé, CS683, F10

## Details of Example

- Case 1
  - $P(c_1=\text{good}|t_2=\text{fail})=p(c_1=\text{good})=.7$ ;  
 test  $t_2$  does not say anything about  $c_1$
  - Utility =  $2000(\text{value of car})-1500(\text{cost of car})-20(\text{cost of test})=480$
- Case 2
  - $P(c_1=\text{bad}|t_2=\text{fail}) = p(c_1=\text{bad}) = 1 - p(c_1=\text{good}) = .3$
  - Utility =  $2000-1500-700(\text{cost of repair})-20 = -220$
- Expected Utility of Chance Node of 1&2
  - $.7 \times 480 + .3 \times -220 = 270$

V. Lammé, CS683, F10

## Details of Example cont

- Case 3
  - $P(c_2=\text{good}|t_2=\text{fail}) =$
  - $P(t_2=\text{fail}|c_2=\text{good}) P(c_2=\text{good})/P(t_2=\text{fail}) =$
  - $(.25 \times .8 = .2) / P(t_2=\text{fail}) =$
  - Normalize  $.2/.34 (= .2 + .14)$ ,  $.14/.34$  (over  $c_2=\text{bad}$  case 4)
  - $.59$
  - Utility =  $1400-1150-20= 230$
- Case 4
  - $P(c_2=\text{bad}|t_2=\text{fail}) =$
  - $P(t_2=\text{fail}|c_2=\text{bad}) P(c_2=\text{bad})/P(t_2=\text{fail}) =$
  - $(.7 \times .2 = .14) / P(t_2=\text{fail}) =$
  - $.41$
  - Utility =  $1400-1150-20-150= 80$
- Expected Utility of Chance Node of 3&4
  - $.59 \times 230 + .41 \times 80 = 168.5$

V. Lammé, CS683, F10

## Details of Example cont

- What is the decision if
  - Decide to do test  $t_2$
  - It comes out false
  - Do you buy  $c_1$  or  $c_2$ ?
    - $E(c_1|\text{test } t_2=\text{fail}) =$  Expected Utility of Chance Node of 1&2 = 270
    - $E(c_2|\text{test } t_2=\text{fail}) =$  Expected Utility of Chance Node of 3&4 = 168.5

V. Lammé, CS683, F10

## Example 2: Buying a car cont.

**Do Test  $T_1$ ; If  $T_1$  fails buy  $C_2$  else buy  $C_1$**

## Decision Networks/Influence Diagrams

- Decision networks or influence diagrams are an extension of belief networks that allow for reasoning about actions and utility.
- The network represents information about the agent's current state, its possible actions, the possible outcome of those actions, and their utility.

V. Lamm, CS683, F10

## Nodes in a Decision Network

- Chance nodes (**ovals**) have CPTs (conditional probability tables) that depend on the states of the parent nodes (chance or decision).
- Decision nodes (**squares**) represent options available to the decision maker.
- Utility nodes (**Diamonds**) or value nodes represent the overall utility *based on the states of the parent nodes*.

V. Lamm, CS683, F10

## Example 3: Taking an Umbrella

Parameters:  $P(\text{Rain})$ ,  $P(\text{WeatherReport}|\text{Rain})$ ,  $P(\text{WeatherReport}|\neg\text{Rain})$ ,  $\text{Utility}(\text{Rain}, \text{Umbrella})$

V. Lamm, CS683, F10

## "Taking an Umbrella" as Decision Tree

Case 1:  $U(\text{Umbrella}|W=\text{Rain}) \cdot P(W=\text{Rain}|WR=\text{Rain}) + U(\text{Umbrella}|W=\text{not Rain}) \cdot P(W=\text{not Rain}|WR=\text{Rain})$

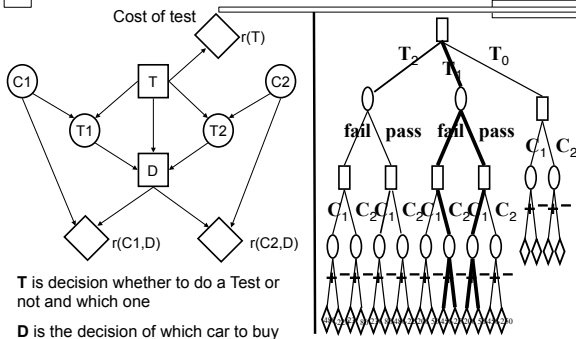

V. Lamm, CS683, F10

## Knowledge in an Influence Diagram

- ◆ Causal knowledge about how events influence each other in the domain
- ◆ Knowledge about what action sequences are feasible in any given set of circumstances
  - Lays out possible temporal ordering of decisions
- ◆ Normative (Utility) knowledge about how desirable the consequences are

V. Lamm, CS683, F10

## Example 2 as an Influence Diagram

T is decision whether to do a Test or not and which one

D is the decision of which car to buy

V. Lamm, CS683, F10

## Decision Trees vs Influence Diagrams

- ◆ Decision trees are not convenient for representing domain knowledge
  - Requires tremendous amount of storage
    - Multiple decision nodes -- expands tree
    - Duplication of knowledge along different paths
      - *Joint Probability Distribution vs Bayes Net*
- ◆ Generate decision tree on the fly from more economical forms of knowledge
  - Depth-first expansion of tree for computing optimal decision

V. Lamm, CS683, F10

## Topology of decision networks

1. The directed graph has no cycles.
2. The utility nodes have no children.
3. There is a directed path that contains all of the decision nodes.
4. A CPT is attached to each chance node specifying  $P(A|\text{parents}(A))$ .
5. A real valued function over parents( $U$ ) is attached to each utility node.

V. Lamm, CS683, F10

## Semantics

- Links into decision nodes are called “information links,” and they indicate that the state of the parent is known prior to the decision.
- The directed path that goes through all the decision nodes defines a temporal sequence of decisions.
- It also partitions the chance variables into sets:  $I_0$  is the vars observed before any decision is made,  $I_1$  is the vars observed after the first and before the second decision, etc.  $I_n$  is the set of unobserved vars.
- The “no-forgetting” assumption is that the decision maker remembers all past observations and decisions. -- Non Markov Assumption

V. Lamm, CS683, F10

## Example 4: Airport Siting Problem

- $P(\text{cost}=\text{high}|\text{airportsite}=\text{Darien}, \text{airtraffic}=\text{low}, \text{litigation}=\text{high}, \text{construction}=\text{high})$

V. Lamm, CS683, F10

## Evaluating Decision Networks

1. Set the evidence variables for the current state.
2. For each possible value of the decision node(s):
  - (a) Set the decision node to that value.
  - (b) Calculate the posterior probabilities for the parent nodes of the utility node.
  - (c) Calculate the expected utility for the action.
3. Return the action/decision with the highest utility.

*Similar to Cutset Conditioning of a Multiply Connected Belief Network*

V. Lamm, CS683, F10

## Imperfect Information Example 5: Mildew

Two months before the harvest of a wheat field, the farmer observes the state  $Q$  of the crop, and he observes whether it has been attacked by mildew,  $M$ . If there is an attack, he will decide on a treatment with fungicides.

There are five variables:

- $Q$ : fair (f), not too bad (n), average (a), good (g)
- $M$ : no (no), little (l), moderate (m), severe (s)
- $H$ : state of  $Q$  plus  $M$ : rotten (r), bad (b), poor (p)
  - **State after action taken whether to treatment or not**
- $OQ$ : observation of  $Q$ ; imperfect information on  $Q$
- $OM$ : observation of  $M$ ; imperfect information on  $M$

V. Lamm: CS403, F10

## Mildew decision model

Maximize ("value of crop" - "cost of action")

V. Lamm: CS403, F10

## One action in general

- ♦ A single decision node  $D$  may have links to some chance nodes.
- ♦ A set of utility functions  $U_1, \dots, U_n$  over domains  $X_1, \dots, X_n$ .
- ♦ Goal: find the decision  $d$  that maximizes  $EU(D=d | e)$ :

$$EU(D|e) = \sum_{X_1} U_1(X_1)P(X_1 | D, e) + \dots + \sum_{X_n} U_n(X_n)P(X_n | D, e)$$

- ♦ How to solve such problems using a standard Bayesian network package?

V. Lamm: CS403, F10

## Multiple decisions -- Policy Generation

Need a more complex evaluation technique since generating a policy (sequence of decisions)

V. Lamm: CS403, F10

## The Domain of Decision Nodes: Options At Decision Node D

- T:  $t_0, t_1, t_2$
- D:
  - If T =  $t_0$  then { Buy 1, Buy 2 }
  - If T =  $t_1$  then {
    - Buy 1 if  $t_1$ =pass else Buy 2,
    - Buy 2 if  $t_1$ =pass else Buy 1,
    - always Buy 1,
    - always Buy 2 }
  - If T =  $t_2$  then {
    - Buy 1 if  $t_2$ =pass else Buy 2,
    - Buy 2 if  $t_2$ =pass else Buy 1,
    - always Buy 1, always Buy 2 }

V. Lamm, CS683, F10

The Next Set of Slides were not covered  
in detail in class and thus will not be  
tested on the final exam

V. Lamm, CS683, F10

## Evaluation by Graph Reduction

Basic idea: (Ross Shachter) Perform a sequence of transformations to the diagram that preserve the optimal policy and its value, until only the UTILITY node remains.

- Similar to ideas of transformation into polytree

Four basic value/utility-preserving reductions:

- ♦ Barren node removal
- ♦ Chance node removal (marginalization)
- ♦ Decision node removal (maximization)
- ♦ Arc reversal (Bayes' rule)

V. Lamm, CS683, F10

## Barren node reduction

- ♦ Let  $X_j$  represent a subset of nodes of interest in an influence diagram.
- ♦ Let  $X_k$  represent a subset of evidence nodes.
- ♦ We are interested in  $P(f(X_j) | X_k)$
- ♦ A node is “barren” if it has no successors and it is not a member of  $X_j$  or  $X_k$ .
- ♦ The elimination of barren nodes does not affect the value of  $P(f(X_j) | X_k)$

V. Lamm, CS683, F10

## Barren Node Removal

V. Lesser, CS683, F10

## 1 Barren Node Removal

$$\sum_D P(A, B, C, D) = P(A)P(B|A)P(C|B, A) \sum_D P(D|C)$$

## 1 Removal into Value Node (by Expectation)

$$V(D) = \sum_X V(X, D) * P(X)$$

Summer Institute on Probability in AI 1994

Inference 1.21

## Notation for Shachter's algorithm

For chance nodes:

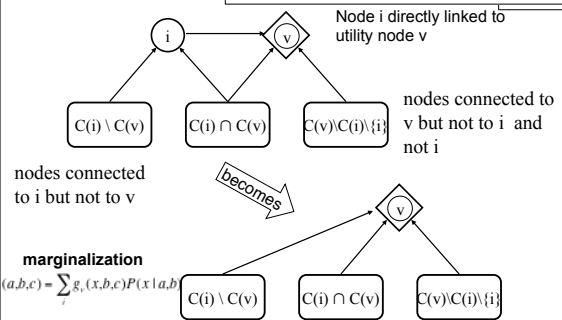

- $S(i)$  = direct successors = children
- $C(i)$  = conditional predecessors = parents

For decision nodes

- $I(i)$  = information predecessors = parents

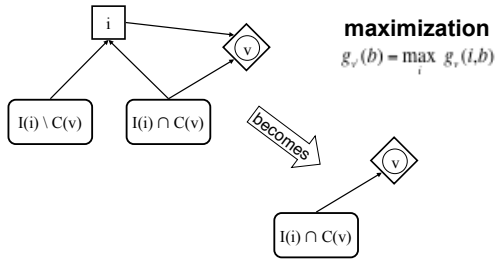

V. Lesser, CS683, F10

## Chance Node Removal

V. Lesser, CS683, F10

## Decision node removal

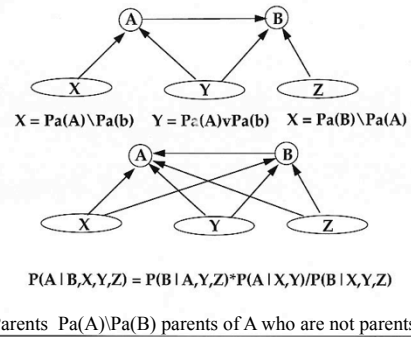

## Arc reversal

- Given an influence diagram containing an arc from  $i$  to  $j$ , but no other directed path from  $i$  to  $j$ , it is possible to transform the diagram to one with an arc from  $j$  to  $i$ . (If  $j$  is deterministic, then it becomes probabilistic.)

## Arc Reversal

## Arc Reversal

### Decision Example

- 1 Reverse X-Y Arc
- 1 Removal of X by Expectation into V
- 1 Removal of D by maximization into V
- 1 gives you the optimal policy for D given Y
