Lecture 8: Search 7

Victor R. Lesser CMPSCI 683 Fall 2010

#### This Lecture

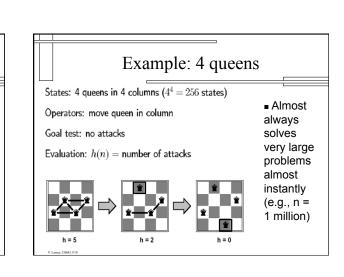

- Continuation of Local Search
  - Hill-Climbing/Iterative Improvement
    - Simulated Annealing (Stochastic Hill Climbing)
  - Beam Search
    - Genetic Algorithm

N. I. ..... CONTRACTOR TO

#### Iterative Improvement Algorithms

- What is the search space
  - Search space of complete solutions vs. partial solutions
- When useful:
  - "Reasonable" complete solution can be generated
    - Importance of good starting point
  - Operator to modify complete solution
  - Some notion of progress
    - Measure of complete solution in terms of constraint violations or an evaluate function

V. Lesser; CS683, F1

#### Hill-Climbing(HC) Search

• The main iterative improvement algorithm is hillclimbing:

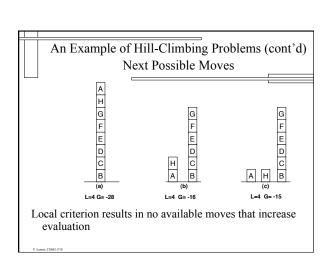

Continually move in the direction of increasing value of all successor states until a maximum is reached.

 This is sometimes called steepest-ascent HC, and is called gradient descent search if the evaluation function is based on minimizing cost rather than maximizing quality.

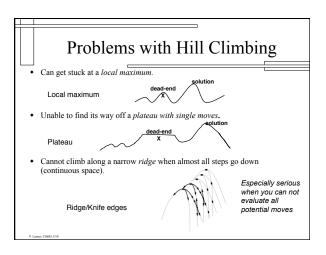

...

# Steepest Ascent Hill-Climbing function Hill-Climbing (problem) returns a state that is a local maximum inputs: problem, a problem local variables: current, a node current ← MAKE-NODE(INITIAL-STATE[problem]) loop do Looks at all successors if Value[neighbor] < Value[current] then return State[current] current ← neighbor

## 

#### Variants of hill-climbing

Ways to overcome the weaknesses:

- Stochastic hill-climbing (Simulated Annealing): choose at random an uphill move among the successors
  - Sometimes take downhill steps
  - You may have to get worse to get better!!
- First-choice hill climbing: generate successors randomly until finding an uphill move
- Random-restart hill climbing: restart search from randomly generated initial states if not making progress

V. Lesser, CS683, F1

#### Simulated Annealing

"Simulated annealing is a variation of hill climbing in which, at the beginning of the process, some downhill moves may be made. The idea is to do enough exploration of the whole space early on so that the final solution is relatively insensitive to the starting state. This should lower the chances of getting caught at a local maximum, a plateau, or a ridge."

V. Lesser, CS683, F10

#### Simulated annealing search

- Generate successors randomly
- Allow "bad" moves with some probability  $e^{\Delta E/T}$ 
  - Proportional to the value (or "energy") difference  $\Delta E$
  - Modulated by a "temperature" parameter T
- Gradually decrease the frequency of such moves and their size by reducing the "temperature"
  - more time goes, less willing to explore non-optimal path
- Originated in modeling physical processes
- Optimal when T is decreased "slowly"

#### Simulated Annealing Algorithm

- 1. Evaluate the initial state. If it is also a goal state, then return it and quit. Otherwise, continue with the initial state as the current state.
- 2. Initialize BEST-SO-FAR as the current state.
- 3. Initialize *T* according to the annealing schedule

#### Simulated Annealing Algorithm (cont'd)

- Loop until a solution is found or until there are no new operators left to be applied in the current state.
  - a) Select an operator (randomly) that has not yet been applied to the current state
  - b) Evaluate the new state. Compute
  - $\Delta E$  = (value of current) (value of new state)
  - If the new state is a goal state, return it and quit.
  - If it is not a goal state but is better than the current state, then make it the current state.

    set BEST-SO-FAR to this new state if better than current BEST-SO-FAR.

  - If it is not better than the current state, then make it the current state with probability  $p' = f(\Delta E, T)$ .
  - c) Revise T according to the annealing schedule
- Return BEST-SO-FAR as the answer.; anytime property

#### Simulated Annealing Algorithm

Idea: escape local maxima by allowing some "bad" moves but gradually decrease their size and frequency

function Simulated-Annealing (problem, schedule) returns a solution state  ${\bf inputs}:\ problem,\ {\bf a}\ problem$ 

schedule, a mapping from time to "temperature" local variables: current, a node

next, a node

T, a "temperature" controlling prob. of downward steps

 $current \leftarrow Make-Node(Initial-State[problem])$ 

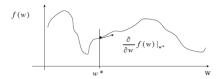

for  $t \leftarrow 1$  to  $\infty$  do  $T \leftarrow schedule[t]$ 

 $\begin{array}{l} T \leftarrow \text{softenested} \\ \text{if } T = 0 \text{ then return } current \\ next \leftarrow \text{a randomly selected successor of } current \\ \Delta E \leftarrow \text{Value}[next] - \text{Value}[current] \end{array}$ 

if  $\Delta E > 0$  then  $current \leftarrow next$  else  $current \leftarrow next$  only with probability  $e^{\Delta E/T}$ 

#### Gradient ascent methods

 Gradient ascent: the same as hill-climbing, but in the continuous parametric space w

• Change the parameter value of w according to the gradient  $w \leftarrow w^* + \alpha \frac{\partial}{\partial w} f(w)|_{w^*}$ 

V. Lesser, CS683, F10

#### Beam Search vs Random-Restart Hill Climbing

- Keep track of K states rather than just one
  - Modified breadth-first, contour created dynamically
- Start with K randomly generated states
- Stop if any goal state
- Multiple Successors generated for each of the k states
- Choose top K successor states in next cycle
- · Contrast with Random Restart
  - Positive -- Sharing information across different searches by choosing top K successor states
  - Negative May eliminate diversity coming from random starting points

...

#### **Evolutionary Computation**

- Beam Search patterned after biological evolution
  - Learning as Search
- Metaphor of Natural Selection
  - Offspring are similar to their parents
  - The more fit are more likely to have children
  - Occasionally random mutations occur

V. Lesser; CS683, F1

#### Genetic (Search) Algorithms

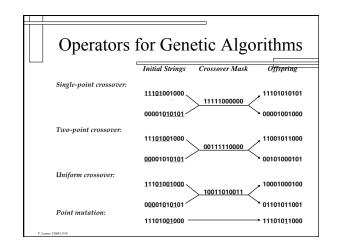

- Localized Beam Search
  - Specialized approach for generating successors and for selecting next states
  - An individual solution is represented by a sequence of "genes".
  - The selection strategy is randomized with probability of selection proportional to "fitness".
  - Individuals selected for reproduction are randomly paired, certain genes are crossed-over, and some are mutated.

V. Lesser, CS683, F10

#### Basic Operation of Genetic Search

- Selection
  - More fit members are likely to be in next generation
- Mutation
  - Random altering of characteristics
- Crossover
  - Combine two members of population
    - Cross-over is probably the key idea
    - Exploit relative independence of certain subproblem solutions imbedded in different members

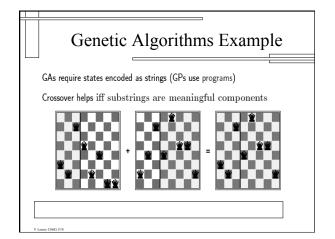

V. Lesser: CS683. F1

### Key Questions for Genetic Search

- What is the fitness function?
- How is an individual represented?
- How are individuals selected?
- How do individuals reproduce?

#### GA (Fitness, Fitness-threshold, p, r, m)

- ◆ GA (Fitness, Fitness-threshold, p, r, m)
  - Initialize: P ← p random hypotheses
  - Evaluate for each h in P, compute-fitness (h)
  - While [max<sub>h</sub> fitness (h)] < Fitness-threshold
    - Select probabilistically select (1-r) p members to add to P<sub>s</sub>
       Pr (h<sub>i</sub>)= fitness (h<sub>i</sub>)/ Sum of fitness of all members of P
    - Crossover: probabilistically select r p/2 pairs of hypotheses from P. For each pair (h<sub>i</sub>,h<sub>k</sub>), produce two offspring by applying the Crossover operator. Add all offspring to P<sub>s</sub>

Lesser CS683, F10

...continued from previous slide

- 3. Mutate: Invert a randomly selected bit in  $m \cdot p$  random members of  $P_s$
- 4. Update:  $P \leftarrow P_s$
- 5. Evaluate: for each h in P, compute Fitness(h)
- Return the hypothesis from *P* that has the highest fitness.

#### Selecting Most Fit Hypotheses

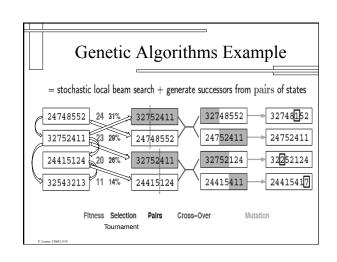

#### Fitness proportionate selection:

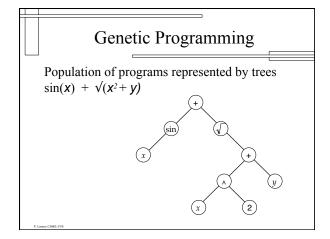

Pr (h<sub>i</sub>)= fitness (h<sub>i</sub>)/ Sum of fitness of all members of P

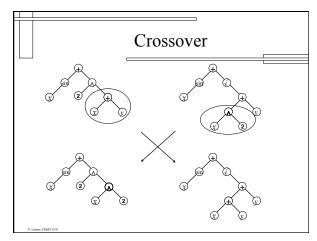

...can lead to crowding (lack of diversity)

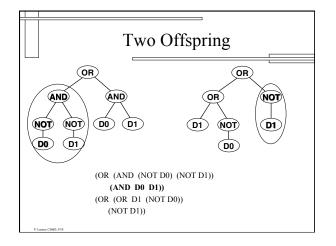

- ◆ Tournament Selection:
  - Pick  $h_1$ ,  $h_2$  at random with uniform probability.
  - With probability p, select the more fit
- Rank Selection:
  - Sort all hypotheses by fitness
  - Probability of selection is proportional to rank

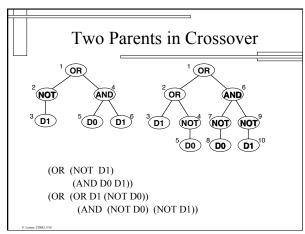

V. Lesser, CS683, F1

#### **Genetic Programming**

More interesting example: design electronic filter circuits

- Individuals are programs that transform beginning circuit to final circuit, by adding/ subtracting components and connections
- Use population of 640,000, run on 64-node parallel processor
- Discovers circuits competitive with best human designs

#### Summary: Genetic algorithms

- Have been applied to a wide range of problems.
- Results are sometimes very good and sometimes very poor.
- The technique is relatively easy to apply and in many cases it is beneficial to see if it works before thinking about another approach.
